

status under each angle: def = defined, impr = net error improves, den? = denominator uncertain (no ratio), und = undefined -- the ratio status; mc? = unresolved Monte Carlo uncertainty (convergence or seed-status disagreement), which is printed instead of the ratio status because it outranks it; n = queries in the shared comparison mask

waveform and acoustic gaps measure the sensitivity of the model-plus-Griffin-Lim pipeline, conditional on the per-query phase seed; the shared phase initialisation removes initialisation noise, but Griffin-Lim is a nonlinear inverse and can amplify a magnitude change. logspec_mad and mag_rel_12 are the Griffin-Lim-free readout of the same shift, computed on the model's direct log-magnitude output. T60: delta = change in the GT-normalised error, percentage points, G = percent of the baseline prediction's T60.
